

Data Visualisation – Assignment 2

Attachment Style and Uses of Music

John Downing, Irene Volpe, Jessica Verschoyle

Question

To what extent is there a relationship between attachment style and uses of music?

Motivation

- "Music is a ubiquitous aspect of all human cultures and has been associated with broad psychological functions, in particular emotion regulation and coping" (Chamorro-Premuzic & Furnham, 2007; p. 175)
- "Attachment style is an important construct for researchers and clinicians interested in individual differences in emotion regulation (Mikulincer & Shaver, 2010; p. 218)

Attachment Style (briefly..)

- Suggests that early experience of caregiver relationships has a lasting effect on abilities to cope with emotion.
- The quality of these experiences – how much we think we can rely on others for security – subconsciously shapes our coping strategy ("attachment style").
- Two dimensions of attachment style: hyper-activating/anxious; deactivating/avoidant.
- If listening to music is a coping strategy, is there any link to attachment style?

Population

- In theory, anyone. No attempt to restrict participation to a known population e.g. Goldsmiths students.
- In practice, likely to be other Data Viz students, plus (Facebook) friends and family.
- Sample unlikely to generalise to target population, potential sources of bias include
 - Bias against people who do not listen to music.
 - Bias against people not in relationships (by nature of attachment questions).
 - Online study; only people with internet access could have responded.
 - Bias towards people who respond to online questionnaires.

Research Method

Questionnaires

- Two existing measures:
 - Adult Attachment Questionnaire (AAQ) (Simpson, Rholes & Phillips, 1996)
 - Uses of Music Inventory (UMI) (Chamorro-Premuzic & Furnham, 2007)
- Also some basic demographics:
 - Age (free numeric text)
 - Gender (select from "Male", "Female", "Not Listed")
 - Country where you grew up (select from list of 257 countries, scraped from www.listofcountriesoftheworld.com)

Adult Attachment Questionnaire (AAQ)

- Self report
- 17 Questions
- 1 to 7 point Likert scale
- 2 constructs being measured:
 - Attachment avoidance
 - Attachment anxiety
- Q1-3 and 5-9 = avoidance
- Q4 & 10-17 = anxiety
- Q1, 3, 4, 12, 14, 16, and 17 reverse keyed (R)
- Mean response from each construct gives score on dimension between 1 and 7

e.g. Avoidance:

- *I'm not very comfortable having to depend on other people.*
- *I don't like people getting too close to me.*
- *I'm comfortable having others depend on me. (R)*

e.g. Anxiety:

- *I often worry that my partner(s) don't really love me.*
- *I usually want more closeness and intimacy than others do.*
- *The thought of being left by others rarely enters my mind. (R)*

Uses of Music Inventory (UMI)

- Self report
- 15 Questions
- 1 to 5 point Likert scale
- 3 constructs being measured:
 - Emotional use of music
 - Cognitive/Intellectual use of music
 - Background use of music
- 5 questions for each construct
- 1 question reverse scored for each construct
- Mean response for each construct gives score on dimension between 1 and 5

e.g. Emotional:

- *Listening to music really affects my mood.*

e.g. Cognitive/Intellectual:

- *I often enjoy analysing complex musical compositions.*

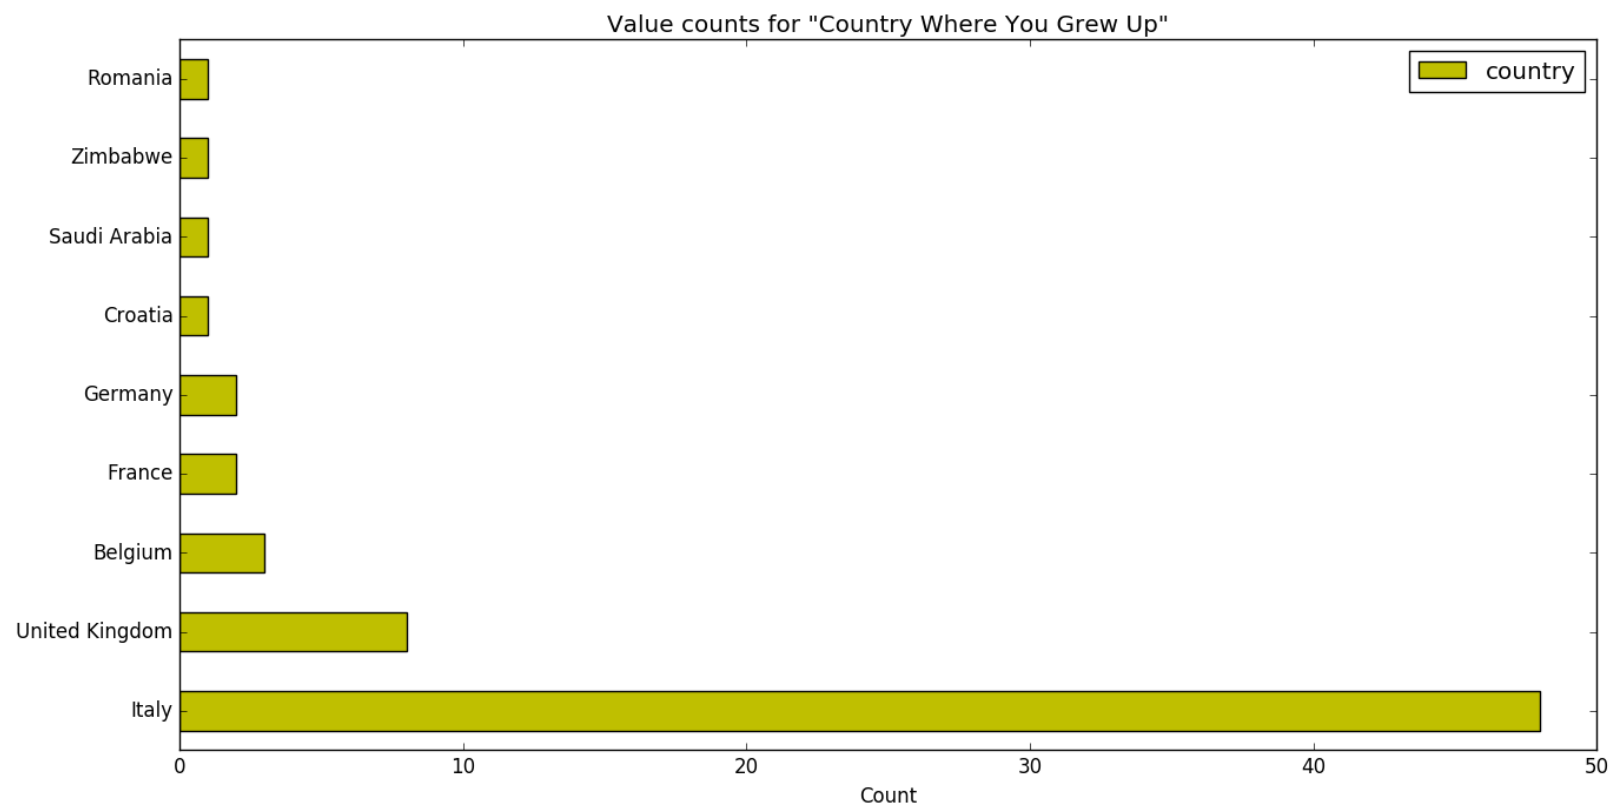

e.g. Background

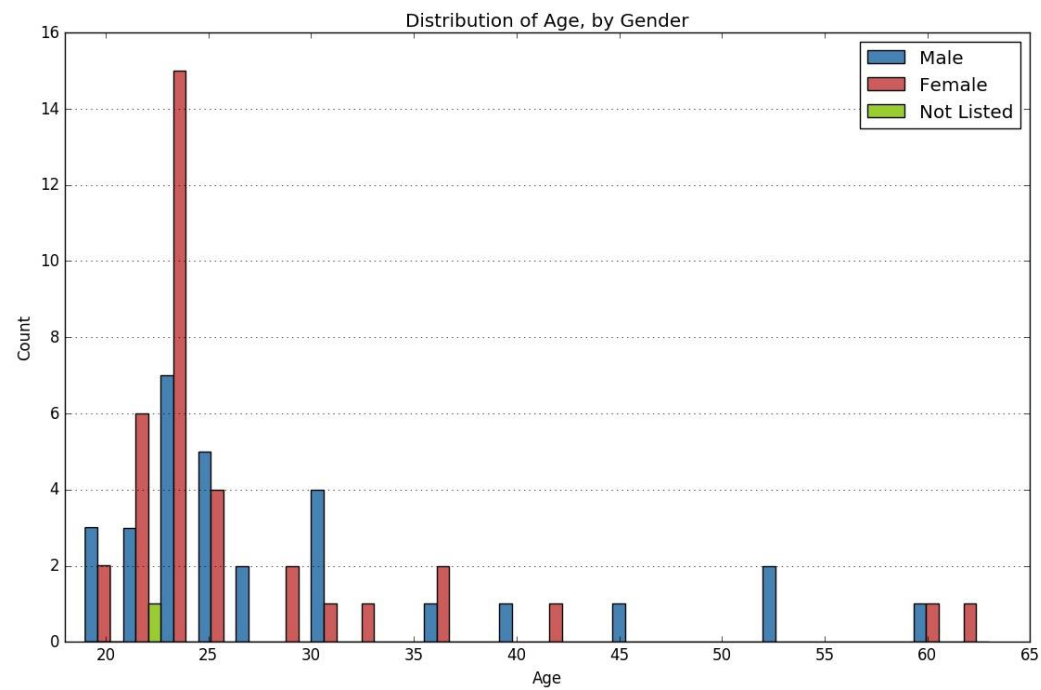

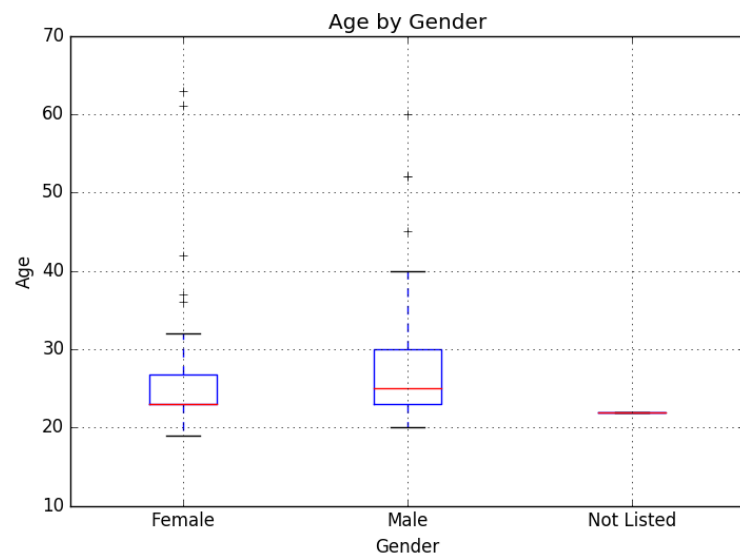

- *If I don't listen to music while I'm doing something, I often get bored.*

Results

Participants

- 68 respondents
- 30 Male, 36 Female, 2 Not Listed
- 1 participant excluded (age of 666; gender of 'Not Listed')
- Remaining aged between 19 and 63 years ($X=28.1$, $SD=10.06$)
 - Similar male/female mean and SD, however much higher peak for Female at mode (23 years).
- Large Italian contingent (48 responses - 20 Male, 27 Female, 1 Not Listed).
 - Age between 19 and 61 ($X=25.5$, $SD=8.06$)
 - Age more normally distributed < 35 years

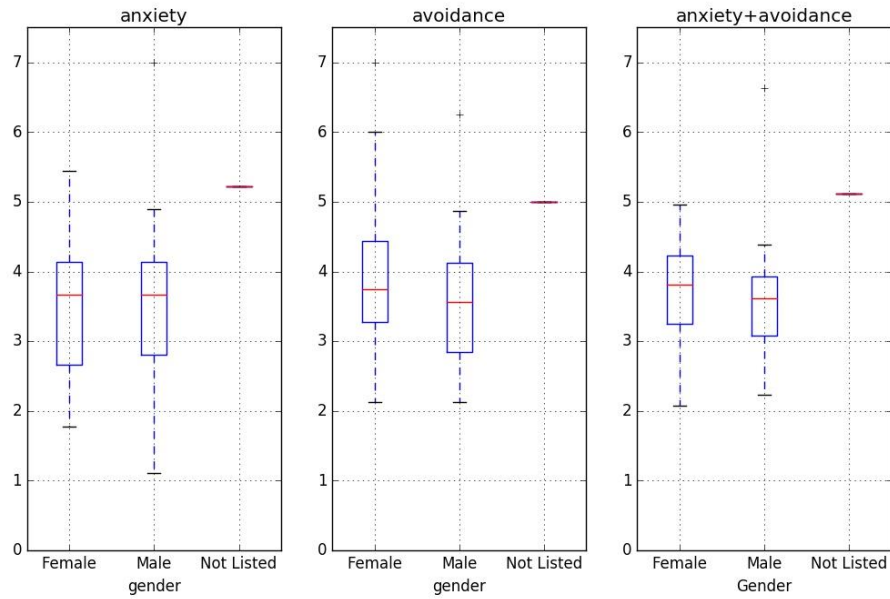

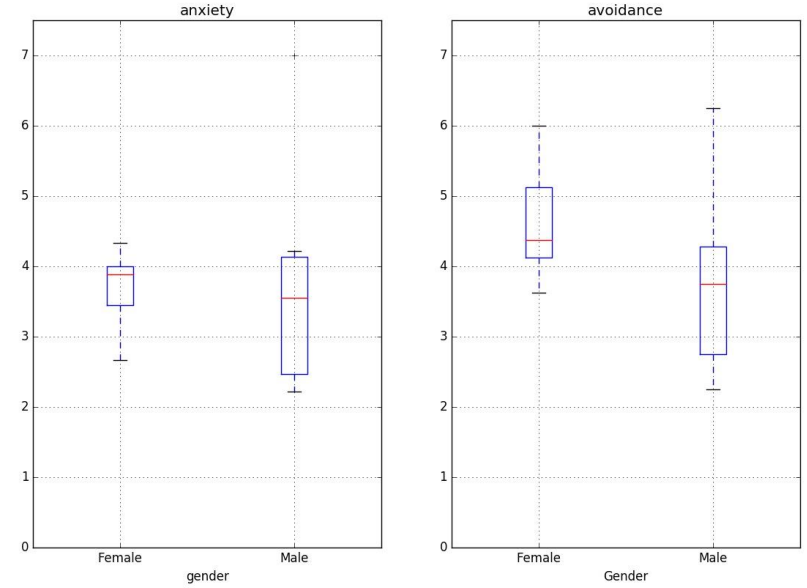

Adult Attachment Questionnaire

- Anxiety
 - Mean score 3.6 out of 7 (SD=0.99)
 - Male (X=3.5, SD=1.08)
 - Female (X=3.5, SD=0.89)
 - Not Listed (X=5.2, SD=0.00)
- Avoidance:
 - Mean score 3.8 out of 7 (SD=1.03)
 - Male (X=3.6, SD=0.96)
 - Female (X=3.9, SD=1.08)
 - Not Listed (X=5.0, SD=0.00)
- Some suggestion of group difference (by gender) in non-Italian participants aged < 35, but sample size (N=11) too small to trust.

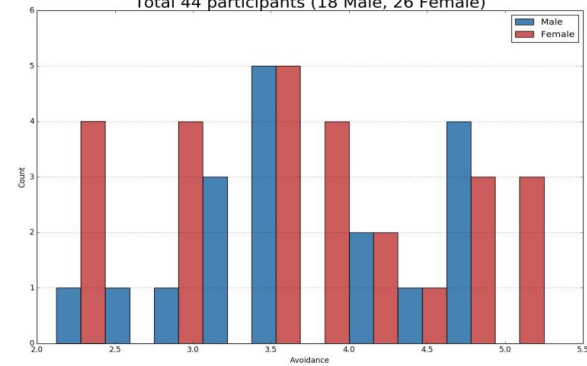

Attachment Dimensions by Gender

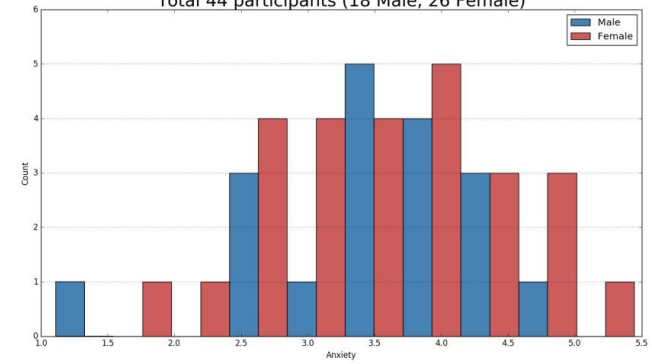

Attachment Dimensions by Gender - Not Italy, Age < 35
total 11 participants (6 Male, 5 Female)

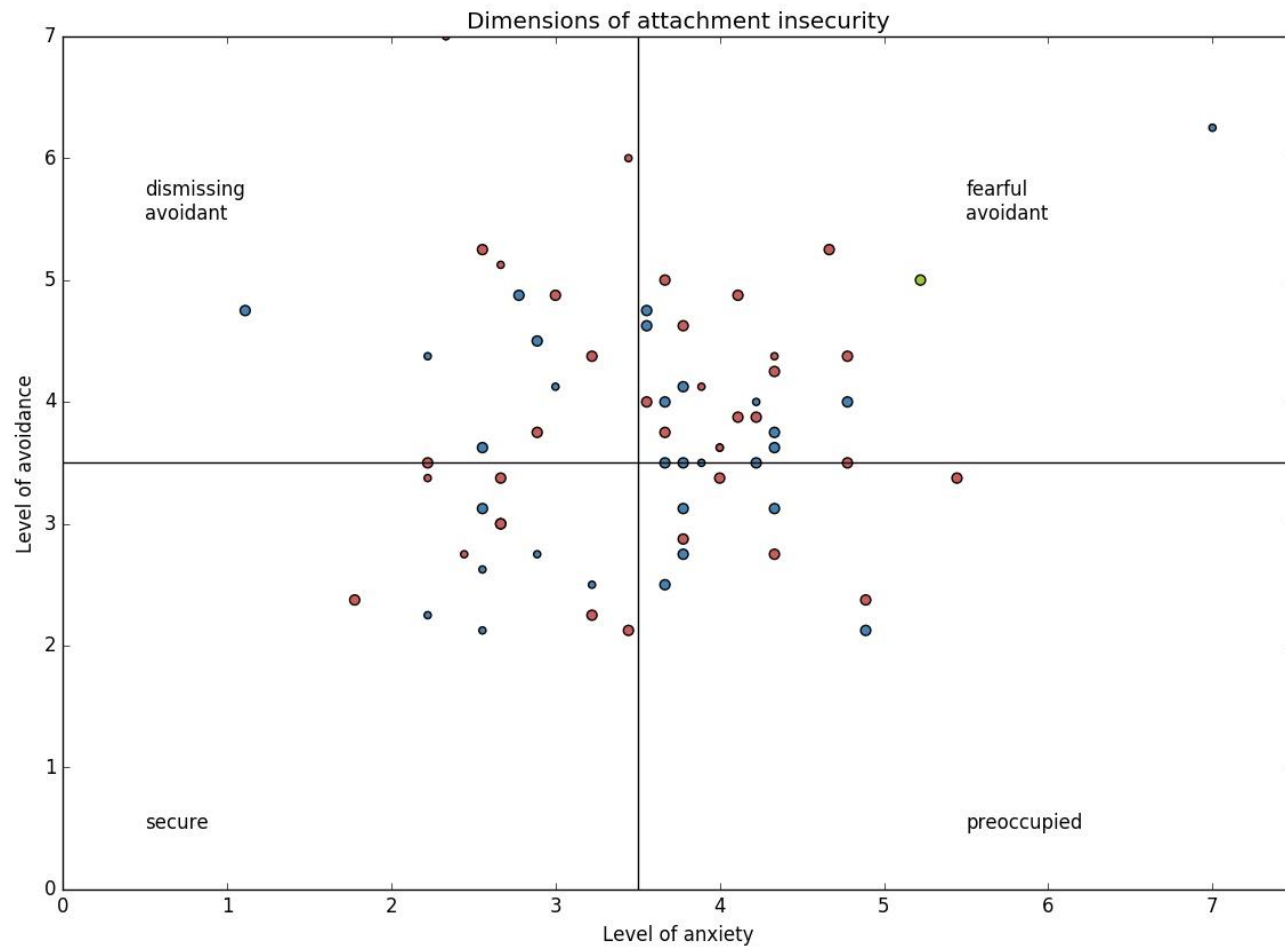

Distribution of Avoidance, by Gender - Italy, Age < 35
Total 44 participants (18 Male, 26 Female)

Distribution of Anxiety, by Gender - Italy, Age < 35
Total 44 participants (18 Male, 26 Female)

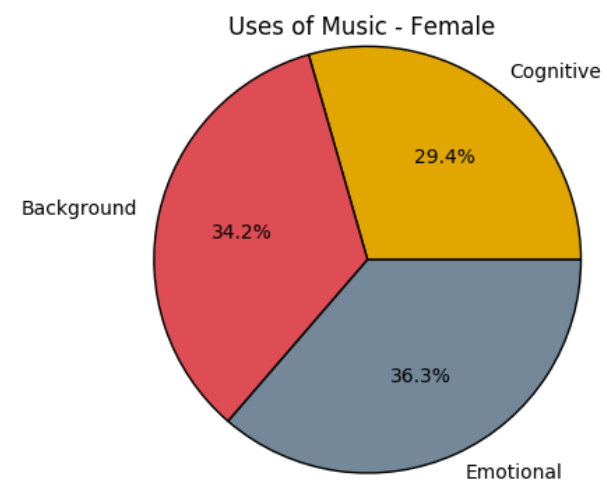

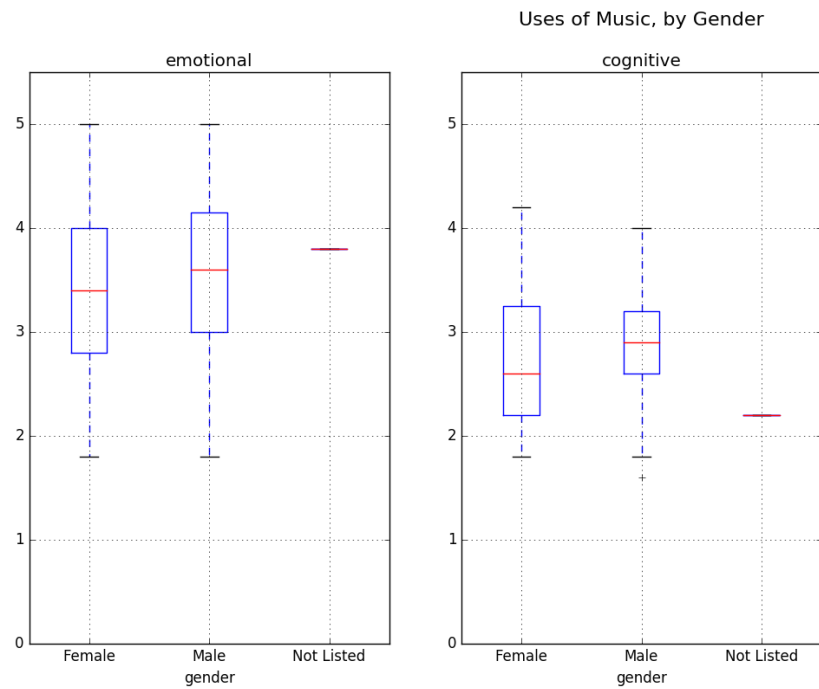

quadrant names suggested by Bartholomew (1990)

Uses of Music Inventory

- Participants reported using music for emotional purposes the most, followed by background and then cognitive.
- Emotional:
 - Male usage proportionally higher than female.
 - Male median score also slightly higher.
 - Similar range, otherwise.
- Cognitive:
 - Lowest median scores for both male and female respondents.
 - Also lowest proportional usage compared to other two categories.
 - Inter-quartile range greater for female.
- Background:
 - Female usage proportionally higher than male.
 - Mean female score higher than male.
 - Range of female scores greater than male.

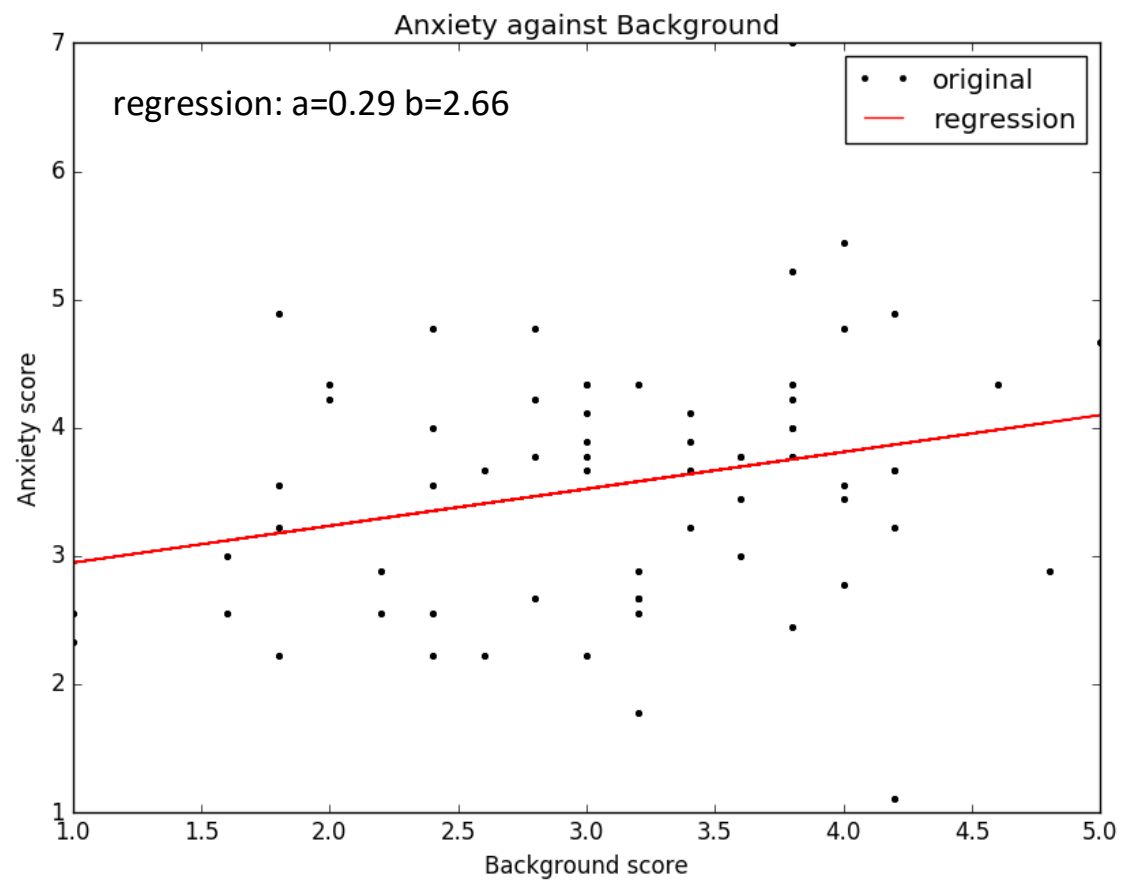

Correlations

- No obvious relationships detected between AAQ and UOM constructs (from eyeballing data)
- However linear regression showed weak correlation between level of attachment anxiety and background use of music ($r=0.26$, $p = 0.034$)
- This increases if sample restricted to Female, Italian, and < 35 years ($N=26$, $r=0.49$, $p = 0.010$).

Scatter matrix for age, attachment, and uses of music

Conclusion

- Some support for relationship between AAQ and UOM, but no strong correlations
- Possible interpretations:
 - There is no relationship
 - We did not have enough participants
 - Our sample was not representative
 - AAQ is not a suitable measure
 - UOM is not a suitable measure
 - Self report measures, generally, are not suitable
